Tip of the Month

Tips to Help Speed up your Computer

If your computer seems slower than it used to be, it probably is. Over time, computers get slower because files become disorganized and resources are consumed by unnecessary software. Fortunately, Microsoft Windows XP includes tools to clean up your computer and restore its performance. The steps in this article will walk you through the use of these tools to tune up your computer and will be continued within the next four months.

Before you do anything, backup your computer. Some of the steps in this article can cause pre-existing but hidden problems to surface, which may keep your computer from starting. A backup allows you to restore your important files in the unlikely event that something does go wrong.

2. Install and run antispyware software
Most programs can be removed using the Add or Remove Programs function accessible from Control Panel, but spyware programs are more stubborn. Windows Defender (a free download from Microsoft) or another antispyware program can detect and remove these programs. You should always have an antispyware program installed, because spyware might install itself on your computer without your knowledge. After you install the antispyware program, run it to detect and remove any unwanted programs.

*If you are unsure, or don't know what a type of a program it is for, don't uninstall it, send an email to: helpdesk@scallycomputechs.com
